Statement of Inquiry: When substances interact, there is evidence that they change as a result of scientific processes

In this unit, we will consider these questions:

These concepts will be covered...

Key concept: Change

Related concepts: Interaction, Evidence

Global Concept: Scientific and technological innovations

This unit will give the opportunity to improve in these skills...

- Communication skills
- Critical-thinking skills

Assessment opportunities in this unit include...

Criterion A: Knowing and Understanding

The Periodic Table of the Elements

1	2	1 H hydrogen 1										3	4	5	6	7	0

* The lanthanoids (atomic numbers 58–71) and the actinoids (atomic numbers 90–103) have been omitted.

The relative atomic masses of copper and chlorine have not been rounded to the nearest whole number.

Acids and Bases Introduction

Acids

Most people are familiar with acids and some of the things that acids do, such as reacting with metals and causing burns if they come in contact with the skin.

Find out where these acids are found and write your answers in this table.

Acids	vinegar Places where found
acetic acid (ethanoic acid)	ants' stings and stinging nettles
formic acid (methanoic acid)	citrus fruits (lemons, oranges, grapefruit)
citric acid	rhubarb leaves and spinach
oxalic acid	the stomach (digestive juices)
hydrochloric acid	grapes and wine (also baking powder)
tartaric acid	muscles after exercise; sour milk
lactic acid	

You may have been surprised to see hydrochloric acid in that list. It is used by the body to digest food. It is of course very dilute. Even the 'dilute acid' in the laboratory is much more concentrated.

In the **laboratory**, the main acids used are:

Acid	Chemical formula	
hydrochloric acid	HCl	These are used a lot
nitric acid	HNO ₃	
sulfuric acid	H ₂ SO ₄	
phosphoric acid	H ₃ PO ₄	These are sometimes used
carbonic acid	H ₂ CO ₃	
nitrous acid	HNO ₂	
sulfurous acid	H ₂ SO ₃	

Bases

You may not be so familiar with the group of chemicals called ***BASES***. Bases are the chemical opposites of acid. They are oxides or hydroxides of metals. Some of the bases normally found in the laboratory are shown in the table below.

Bases	Chemical formula	solubility
copper(II) oxide	CuO	These bases are <i>insoluble</i> in water
iron(II) oxide	FeO	
zinc oxide	ZnO	
sodium hydroxide	NaOH	These bases are <i>soluble</i> in water
potassium hydroxide	KOH	
calcium hydroxide	Ca(OH) ₂	

The bases that dissolve in water are given a special name. They are called ***ALKALIS***. Sodium hydroxide, potassium hydroxide, and calcium hydroxide are all ***ALKALIS***. One other alkali which is a little unusual is ammonium hydroxide, NH₄OH. It does not contain a metal like the other bases but is a solution of ammonia gas (NH₃) in water.

pH Indicators

Aim:

To describe the use of litmus, universal indicator & phenolphthalein to identify acids & alkalis

Background Scientific Information:

The presence of acids or alkalis may be shown using **INDICATORS**. An indicator changes from one colour when mixed with an acid, to another colour when mixed with an alkali.

e.g. litmus, methyl orange and phenolphthalein

pH and the strength of acids and alkalis

Different acids have different strengths, e.g. sulphuric acid is a strong acid and citric acid is a weak acid. The same applies to alkalis. Some are strong, some are weak. Sometimes it is useful to know the strength of acids or alkalis. Unfortunately, indicators such as litmus, methyl orange and phenolphthalein do not tell us which acids and alkalis are strong and which are weak. However, there is another indicator called Universal Indicator that can be used to tell the difference between strong and weak acids and alkalis.

Universal Indicator gives a different colour depending on the strength of the acid or alkali. The colour can be compared with a chart from which you can read a number known as the pH number.

Colour in this chart

1	2	3	4	5	6	7	8	9	10	11	12	13	14
STRONG ACID		WEAK ACID			NEUTRAL			WEAK ALKALI		STRONG ALKALI			

Method:

1. Quarter fill three test tubes with distilled water.
2. Add a few drops of universal indicator to this first test tube and record the colour in the table below.
3. Repeat using the phenolphthalein indicator.
4. Line up one small piece of red and one small piece of blue litmus paper on a white tile.
6. Using a glass rod, take a drip of distilled water from the third test tube and place this onto both pieces of litmus paper. Record the colour of both pieces of paper in the table. Rinse the glass rod each time.
7. Repeat the experiment by quarter filling three new test tubes with the other substances listed in the table below. Only test one substance at a time.

Results:

Substance to be tested	Colour with universal indicator (UI) solution	Colour with phenolphthalein solution	Colour of red litmus paper after adding substance	Colour of blue litmus paper after adding substance	pH	Type of substance
hydrochloric acid (teacher demo)	red	colourless	stays red	turns red		acid
distilled water	green	colourless	stays red	stays blue		neutral
sodium hydroxide	purple	pink	turns blue	stays blue		alkali
salt solution	green	colourless	stays red	stays blue		neutral
lemon juice	orange	colourless	stays red	turns red		acid
vinegar	orange	colourless	stays red	turns red		acid
washing powder in solution	blue	pink	turns blue	stays blue		alkali

Acids, Alkalis and Indicators - EXTENSION

1. The sentences on the right are to do with acids and alkalis. Three describe acids, and the other three describe alkalis.

Make a table with the headings shown below, then copy the sentences into the correct columns. You will need four lines in your book.

2. Acids and alkalis often have one of these hazard symbols on the bottle.

Copy the symbols into your book. Find out what each one means. Write down what they mean next to the symbols in your book.

3. For each of these substances, write down whether they are:

strongly acidic, weakly acidic, neutral, weakly alkaline, or strongly alkaline.

- | | | |
|-----------------------------|-----------------|----------------------|
| a) grapefruit juice, pH 3.0 | c) beer, pH 5.0 | e) sea water, pH 8.5 |
| b) blood, pH 7.4 | d) rain, pH 6.2 | f) saliva, pH 7.0 |

4. Universal indicator paper has the following range of colours:

colour	red	orange	yellow	green	blue	purple
pH	0 – 4	5	6	7	8 – 10	11 – 14

An experiment to find the pH of some substances gave these results:

substance	colour of universal indicator paper
orange juice	red
egg white	blue
oven cleaner	purple
milk	yellow

For **each** substance, write down the **name** of the substance, its **pH**, and what the pH **means**.

5. Copy the table below into your book. Complete your table to show the colour that each indicator turns (if it does) in acidic, neutral and alkaline solutions.

	blue litmus paper	red litmus paper	universal indicator
acidic			
neutral			
alkaline			

6. Write a brief description of an experiment you have done to find out whether different substances are acidic, neutral or alkaline. You can do a diagram to help your answer if you want to.

Space for notes about acids, alkalis and indicators

Acids have pH below 7 and turn blue litmus red. Alkalis have pH above 7 and turn red litmus blue. Universal indicator measures pH; phenolphthalein is colourless in acid, pink in alkali.

Acids have a pH below 7, e.g. hydrochloric, sulfuric and nitric acid.

Alkalis have a pH above 7, e.g. sodium hydroxide and potassium hydroxide.

A neutral solution has pH 7, e.g. pure water.

Acids turn blue litmus red; alkalis turn red litmus blue.

Universal indicator: red/orange in acid, green at pH 7, blue/purple in alkali.

Phenolphthalein is colourless in acid and pink in alkali.

pH scale runs 0-14; the lower the pH the more acidic, the higher the more alkaline.

Acid + metal $\rightarrow$ salt + hydrogen; acid + carbonate $\rightarrow$ salt + water + carbon dioxide.

Acid + alkali $\rightarrow$ salt + water (neutralisation).

Indicators are dyes that change colour at different pH values.

Neutralisation

Aim

Recall that neutralisation reactions produce heat (thermal energy) (are exothermic). Describe how to use the temperature rise to determine the point of neutralisation of an acid and an alkali. Draw a line graph of experimental results with straight lines of best fit. Make a conclusion by explaining what your results show.

Introduction

When an **acid** reacts with an **alkali** a **neutralisation** reaction occurs:

Suggest, using previous knowledge, how you could find the volume of acid needed to exactly neutralise 20cm³ of an alkali.

*Add acid to the alkali in small portions, measuring the temperature after each addition. When the temperature stops rising
(maximum) the alkali is exactly neutralised; read the volume of acid added.....*

.....

Neutralisation reactions **produce heat** and the temperature rises during the reaction. The reactions are said to be **exothermic**. This heat can also be used to determine the volume of acid required for neutralisation.

What to do:

1. Obtain a polystyrene cup with a lid and sit it in a 250cm³ beaker to give it stability.
2. Use a 25cm³ measuring cylinder to carefully measure out 20cm³ of sodium hydroxide solution and pour this into the polystyrene cup.
3. Record the temperature of the alkali.
4. Using a 10cm³ measuring cylinder carefully measure out 5cm³ of hydrochloric acid solution. Pour this into the sodium hydroxide solution and stir.
5. Record the new temperature.
6. Repeat steps 4 & 5 until you have added a total of 40cm³ of hydrochloric acid.

You need to measure out the 5cm³ portions of acid and add them as quickly as possible to obtain the most accurate temperature change.

Materials required

Polystyrene cups + lids
250cm³ beakers
Thermometers
25cm³ and 10cm³ measuring cylinders
Glass rod
2 teat pipettes
1M hydrochloric acid
1M sodium hydroxide

Safety:

Sodium hydroxide is corrosive
Hydrochloric acid is an irritant
Wear safety goggles

Results:

Volume of sodium hydroxide used =

20 cm³

Volume of acid added (cm ³)	Temperature of solution (°C)
0	20
5	22
10	24
15	26
20	28
25	27
30	26
35	25
40	24

Analysis of your results:

- 1) Why was a polystyrene cup used in the experiment rather than a glass beaker?

~~Polystyrene is a good insulator, so less heat is lost to the surroundings, keeping the temperature readings higher and the results more accurate.~~

.....

.....

- 2) Plot a graph of volume of acid (x-axis) vs temperature of solution (y-axis) Draw **TWO** best fit straight lines through the points, starting from both ends of the graph, meeting at a peak. The point where the lines cross on the graph indicates the maximum temperature reached in the experiment.

~~Draw one best-fit line through the rising points and one through the falling points; where they cross read the volume of acid that just neutralises the alkali (maximum temperature).~~

- 3) What was the maximum temperature in your experiment (**from the graph**)?

~~28 °C (where the two lines of best fit meet at the peak of the graph).~~.....

- 4) What volume of hydrochloric acid exactly neutralised the 20cm³ of sodium hydroxide solution?
How can you tell?

~~20 cm³: the temperature reached its maximum at this volume (the two best-fit lines crossed at the peak) and then began to fall as excess acid was added.~~

.....

.....

5) What was the reacting ratio of volume of sodium hydroxide: volume of hydrochloric acid?

1 : 1 (20 cm³ sodium hydroxide : 20 cm³ hydrochloric acid).....

6) Why did the temperature start to fall after neutralisation?

After neutralisation all the alkali has reacted, so no more heat is produced; the excess acid is at room temperature and heat is lost to the surroundings, cooling the solution.....

7) Write a word equation for the reaction.

sodium hydroxide + hydrochloric acid → sodium chloride + water.....

8) The chemical equation for this reaction is:

This equation shows a ratio of 1 HCl reacting with 1 NaOH. Does this agree with what you obtained in the experiment? Explain.

Yes. The equation shows 1 HCl reacting with 1 NaOH, and equal volumes (1:1 ratio) of the 1 M solutions reacted, so the experiment agrees with the equation.

9) Suggest 3 reasons that the results of this experiment are not totally accurate, and suggest ways to improve the accuracy.

(i) Heat is lost to the surroundings during the experiment, so the maximum temperature is lower than expected. Improve by insulating the cup and adding a lid with a hole for the thermometer.....

(ii).....

Some acid or alkali is left in the measuring cylinders, so the exact volumes added are not measured. Improve by rinsing with distilled water or using a burette.

(iii).....

The temperature is read after a delay, so heat is lost before each reading. Improve by reading the thermometer straight after stirring or using a data logger.

Properties of Metal and Non Metal Elements

Your task is to fill this table to compare the properties of metals and non-metals. You might use the internet. (*This is a revision of work you did in Year 8.*)

Property	Metal	Non-metal
Are they usually solids, liquids or gases at room temperature?	usually solids (mercury is the exception) Metals are usually solids at room temperature (mercury is the only liquid metal).	usually gases or solids (bromine is a liquid)
Do they usually have high or low melting points ?	high	low
Do they usually conduct electricity ?	yes, they conduct electricity Metals usually conduct electricity - they are conductors.	no (except graphite)
Do they usually conduct heat ? (i.e. conductor or insulator)	good conductors Metals usually conduct heat well - they are good thermal conductors.	insulators (poor conductors)
Are they usually flexible or brittle ?	flexible Metals are usually flexible (malleable), not brittle.	brittle
Can they usually be shaped by hitting them with a hammer? This property is called malleability .	yes, metals are malleable Metals can be shaped by hitting them with a hammer - this property is malleability.	no, they shatter when hammered
Sonorous - do they make a sound if you hit them?	yes, metals are sonorous	no
Are they usually magnetic ?	only some (iron, cobalt and nickel)	no
Are their oxides usually acids or bases ? (Remember an alkali is a soluble base.)	their oxides are bases (alkalis if soluble)	their oxides are acids

Metals in the Home Card Activity

· Card activity: match each metal card to its use in the home, explaining which property makes it suitable (e.g. copper conducts electricity so it is used in wires).

	this hamster is kept in its cage by thin metal bars	strong
	copper, steel and aluminium are used for saucepans	malleable – can be bent into different shapes
	ladders are often made from aluminium	shiny
	the pins and cables in this plug are metal	strong but lightweight
	iron is used to make garden gates	good conductor of heat
	jewellery is made from different metals	ductile – can be stretched into thin wires
	bells and gongs are made of metal	good conductor of electricity
	radiators are made of metal	sonorous – they 'ring' when hit

Marketing Metals - Making and Presenting Task Sheet

Aim: Formulate a link between uses of metals and their properties. Suggest why particular metals are used for certain purposes. Present information clearly and logically

We use metals for so many things but why is that?

For example, why do we use metals to make saucepans or church bells?

Why are car bodies made of so much metal?

Imagine you have just discovered a metal; the world has never seen any metals before.

Your Task:

Design an advertising poster which will tell everyone exactly what metals are and what they can be used for.

- ☐ Include the properties all metals have.
- ☐ Also include properties only some metals have, giving specific examples.
- ☐ Link each property to a possible use, giving examples of where they could be used (obviously they already are, but just pretend!).
- ☐ Give reasons OR explanations OR use detailed scientific knowledge for why metals would be good for the uses you suggest.

The detail you give will depend on the level you are working at:

- 'reasons' **novice level**
- 'explanations' **confident level**
- 'detailed scientific knowledge' **expert level**

Use the 'ECN' Learning Ladder on the next page to help you do your best.

Because metals have useful properties: they are strong, malleable and good conductors of heat and electricity.

Saucepans: metal conducts heat well and is strong. Church bells: metal is strong, castable and rings clearly.

Use your own words throughout the project and ensure any external sources of information are referenced accurately.

'ECN' LEARNING LADDER

Assessment level	The types of things you can do:
Expert	• Design a detailed poster, drawing on detailed scientific knowledge and understanding. • Explain at least seven properties of metals. • Link these properties to uses of metals, using some particle diagrams to explain why they are suitable. • Compare the suitability of metals for uses, considering more than one property. • Use a range of scientific words, symbols and units accurately.
Confident	• Design a poster, drawing on scientific knowledge and understanding. • Explain at least five properties of metals. • Link these properties to uses of metals. • Explain why some metals with the same properties may be better than others at given jobs. • Use a range of appropriate scientific words, symbols and units.
Novice	• Design a simple poster, drawing on some scientific knowledge and understanding. • Describe at least three properties of metals. • State roles that metals are suitable for, giving a reason. • State why some metals are not suitable for certain uses. • Use some appropriate scientific words, symbols and units.

Space for notes/diagrams about metals

Metals are shiny, malleable, sonorous, good conductors of heat and electricity, with high melting points. Non-metals are dull, brittle, poor conductors. Metal oxides are basic. Only iron, cobalt and nickel are magnetic.

Metals are shiny (lustrous), strong materials; most are solids at room temperature.

Metals are good conductors of heat and electricity.

Metals are malleable (hammered into sheets) and ductile (drawn into wires).

Metals usually have high melting and boiling points and are dense.

Metals react with oxygen to form metal oxides, e.g. $2\text{Mg} + \text{O}_2 \rightarrow 2\text{MgO}$.

Metals above hydrogen in the reactivity series react with acids to give hydrogen.

A more reactive metal displaces a less reactive metal from its compound.

Metals react with water or steam to form a metal hydroxide or oxide plus hydrogen.

Uses depend on properties: copper for wires, aluminium for foil, iron for bridges.

Reactivity series: potassium, sodium, calcium, magnesium, zinc, iron, copper, gold.

Metals in Action Card Activity

Look at each of the **'Fact cards'**. Each of the **'Reason cards'** matches one Fact card.

Fact 1:

Ships made of iron sometimes have blocks of magnesium attached to the hull.

Fact 2:

Iron can be galvanised by coating it with zinc. This can protect the iron and stop it rusting.

Fact 3:

Steel cans are sometimes coated with tin. Dented cans can be dangerous because rust can get into the food.

Fact 4:

Although aluminium is more common in the ground than iron, in Victorian times aluminium was a very expensive metal.

Fact 5:

Ancient gold jewellery is often in very good condition when it is discovered.

Fact 6:

The bronze age came before the iron age.

Reason A

Zinc is a more reactive metal than iron. The zinc will react first so that the iron is protected.

Reason B

Tin is less reactive than iron, so rust will not affect the metal can in normal conditions. When the can is dented, the iron can be exposed, and rust can get into the food.

Reason C

Gold is an unreactive metal. Even after thousands of years it doesn't react with air or water.

Reason D

Aluminium is a reactive metal and it is very difficult to extract it from its compounds without modern technology.

Reason E

Magnesium is a reactive metal. The magnesium block reacts with the water before the iron. When the block has all reacted, it can be replaced before the hull of the ship gets damaged.

Reason F

Bronze is mostly made of copper. Copper is an unreactive metal. It is possible to make bronze by heating some types of rock in a fire. Iron ore has to be heated to a much higher temperature to make iron.

Writing Chemical Formulae

Carbon dioxide is a compound made from one atom of carbon and two atoms of oxygen.

The chemical symbol for carbon is **C**.

The chemical symbol for oxygen is **O**.

So the formula for carbon dioxide is **CO₂**.

The number **2** is written **subscript**.

This means it is smaller and written below the line.

The number always comes **after** the element symbol it refers to.

It tells us how many atoms of that element there are in the compound.

If there are no numbers after an element symbol, we know there is only one atom of that element in the compound.

Write the formula for each compound. You can find the symbols for each element on the periodic table.

Compound	Number of Atoms	Formula
carbon dioxide	1 atom of carbon 2 atoms of oxygen	CO ₂
silver bromide	1 atom of silver 1 atom of bromine	CO ₂
water	2 atoms of hydrogen 1 atom of oxygen	AgBr
copper (II) chloride	1 atom of copper 2 atoms of chlorine	H ₂ O
ammonia	1 atom of nitrogen 3 atoms of hydrogen	CuCl ₂
iron (III) oxide	2 atoms of iron 3 atoms of oxygen	NH ₃
benzene	6 atoms of carbon 6 atoms of hydrogen	Fe ₂ O ₃
zinc carbonate	1 atom of zinc 1 atom of carbon 3 atoms of oxygen	C ₆ H ₆
calcium sulfate	1 atom of calcium 1 atom of sulfur 4 atoms of oxygen	ZnCO ₃
potassium nitrate	1 atom of potassium 1 atom of nitrogen 3 atoms of oxygen	CaSO ₄
sodium sulfate	2 atoms of sodium 1 atom of sulfur 4 atoms of oxygen	KNO ₃
zinc thiosulfate	1 atom of zinc 2 atoms of sulfur 3 atoms of oxygen	Na ₂ SO ₄
guanine	5 atoms of carbon 5 atoms of hydrogen 5 atoms of nitrogen 1 atom of oxygen	zinc thiosulfate = ZnS ₂ O ₃ ; guanine = C ₅ H ₅ N ₅ O

Writing Equations

Description	If a metal reacts with oxygen, the product is a metal oxide.
General equation	metal + oxygen · metal oxide
Word equation	magnesium + oxygen · magnesium oxide
Chemical equation	$2\text{Mg} + \text{O}_2 \cdot 2\text{MgO}$

Description	If a metal reacts with water the products are a metal hydroxide and hydrogen.
General equation	metal + water · metal hydroxide + hydrogen
Word equation	sodium + water · sodium hydroxide + hydrogen
Chemical equation	$2\text{Na} + 2\text{H}_2\text{O} \cdot 2\text{NaOH} + \text{H}_2$

Description	If a metal reacts with an acid the products are a salt and hydrogen.
General equation	metal + acid · salt + hydrogen
Word equation	zinc + hydrochloric acid · zinc chloride + hydrogen
Chemical equation	$\text{Zn} + 2\text{HCl} \cdot \text{ZnCl}_2 + \text{H}_2$

Description	When a metal oxide reacts with an acid the products are a salt and water.
General equation	metal oxide + acid · salt + water
Word equation	copper(II) oxide + sulfuric acid · copper(II) sulfate + water
Chemical equation	$\text{CuO} + \text{H}_2\text{SO}_4 \cdot \text{CuSO}_4 + \text{H}_2\text{O}$

Description	When a metal carbonate reacts with an acid, there are three products: a salt, water and carbon dioxide.
General equation	metal carbonate + acid · salt + water + carbon dioxide
Word equation	calcium carbonate + hydrochloric acid · calcium chloride + water + carbon dioxide
Chemical equation	$\text{CaCO}_3 + 2\text{HCl} \cdot \text{CaCl}_2 + \text{H}_2\text{O} + \text{CO}_2$

Balancing Chemical Equations

This sheet shows you the steps to follow when you want to write a balanced symbol equation for a chemical reaction. Here is a worked example

Question: What is the balanced equation for the reaction of methane with oxygen?

Answer:

Step 1 Write down the equation in words

To do this, you need to know the names of the reactants and products

methane + oxygen → carbon dioxide + water

Step 2 Write down the formulae of the reactants and products

You can look up the formulae in a table of data.

$\text{CH}_4 + \text{O}_2 \rightarrow \text{CO}_2 + \text{H}_2\text{O}$ We cannot change the formulae to balance the equation

Step 3 Check to see if the equation needs balancing

Count the atoms on both sides of the equation.

Left hand side

1 carbon atom
4* hydrogen atoms
2* oxygen atoms

Right hand side

1 carbon atom
2* hydrogen atoms
1* oxygen atom

***Not balanced** the numbers of hydrogen and oxygen atoms do not match

If the equation is not balanced (as in this example), go to step 4. If it is already balanced go to step 5.

Step 4 Balance the equation

You must not change any of the formulae to balance the equation. You balance the equation by writing numbers in front of the formulae. These numbers refer to the whole formula.

- Each methane molecule has only one carbon atom so we get one molecule of carbon dioxide
- 4 hydrogen atoms are enough to make 2 water molecules
- There are 4 oxygen atoms on the right, so we need 2 oxygen molecules on the left

$\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O}$

Left hand side

1 carbon atom
4 hydrogen atoms
4 oxygen atoms

Right hand side

1 carbon atom
4 hydrogen atoms
4 oxygen atoms

Balanced! - we now have the same numbers of each atom on both sides of the equation.

Step 5 Add state symbols

These normally show the states of the reactants and products at room temperature

$\text{CH}_4(\text{g}) + 2\text{O}_2(\text{g}) \rightarrow \text{CO}_2(\text{g}) + 2\text{H}_2\text{O}(\text{l})$

We use (g) for a gas, (s) for a solid, (l) for a liquid and (aq) for a solution of something dissolved in water.

$\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O}$ (methane + oxygen → carbon dioxide + water).

Balancing Chemical Equations

What to do: Balance the following equations by putting large numbers in front of the formulae. Remember that you can never change any of the formulae.

Extension:

Rockets Investigation

Introduction:

The combustion reaction of hydrogen and oxygen is used to produce the explosive energy needed to power spaceships. The reaction is also being engineered to serve as a source of continuous energy for fuel cells in electric vehicles. In this investigation, you will generate microscale quantities of hydrogen and oxygen and test their explosive nature in mixtures of various proportions. The goal is to find the most “powerful” gas mixture and use it to launch a rocket across the room.

Q1. Give the word equation for these two gases reacting to make water:

hydrogen + oxygen → water ($2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$)

Hydrogen, the most abundant element in the universe, is a colourless, odourless gas. It is combustible, which means that it readily burns. Hydrogen gas is conveniently generated in the lab by the reaction of zinc metal with hydrochloric acid.

Q2. Balance the chemical equation that we will use to generate hydrogen:

hydrochloric acid + zinc → zinc chloride + hydrogen

Q3. What is the chemical test for hydrogen gas?

Hold a lighted splint in the gas; hydrogen burns with a squeaky pop.

Oxygen, the most abundant element on Earth, is also a colourless, odourless gas. Oxygen gas supports combustion which means it must be present for materials to burn. Small quantities of oxygen gas are conveniently generated in the lab by the decomposition of hydrogen peroxide using a manganese oxide catalyst.

Q4. Balance the chemical equation that we will be used to generate oxygen:

hydrogen peroxide → oxygen + water

Q5. What is the chemical test for oxygen gas?

Place a glowing splint in the gas; the splint relights if oxygen is present.

**Materials:****To prepare hydrogen gas:**Hydrochloric acid (about 15 cm³ of 2 M acid)

Zinc metal (about 4 g provided in test tube)

One hole bung to fit test tube

To prepare oxygen gas:Hydrogen peroxide H₂O₂ (about 15 cm³ of 10 vol solution)

Manganese oxide catalyst (<0.01 g provided in test tube)

One hole bung to fit test tube

The rockets:

Test tube rack

3x calibrated pipette bulbs

Lots of paper towels

For launch:

Ignition switch (one set up in corridor)

Tape measure in corridor

Safety:

Hydrochloric acid is corrosive.

Hydrogen peroxide is an irritant.

**Wear goggles at
all times!**

Also, keep out of range of the rockets
when firing!

Method PART 1:*Make your hydrogen and oxygen gas generators*

- Add hydrochloric acid to the zinc so that the tube is about $\frac{3}{4}$ full (see diagram below).
- Stopper the test tube with the one-hole bung.
- Add hydrogen peroxide to the manganese oxide so the test tube is approximately $\frac{3}{4}$ full.
- Stopper this test tube with another one-hole bung.

To generate hydrogen gas:To generate oxygen gas:

**Method PART 2:**

Fill and test rockets with pure oxygen and pure hydrogen.

- e) Completely fill a pipette bulb with water. Then place the bulb over the gas delivery tube to collect hydrogen gas by the downward displacement of water.
- f) As the bubbles enter the pipette bulb, the water will flow out of the bulb and down the sides of the test tube onto the paper towels.
- g) Once full of hydrogen gas, remove the pipette bulb and quickly seal the hole with your finger.
- h) Take a second rocket, but this time fill it completely with oxygen gas only. Seal the hole as before.
- i) Quickly open the hole of the hydrogen rocket and hold a lit splint near the opening. Note your observations in the table below.
- j) Repeat with the oxygen rocket, but this time introduce a glowing splint. You may need to squeeze the gas gently over the glowing splint. Record your observations.

Pure gas	Observations
hydrogen (H ₂)	The hydrogen ignites and burns with a loud pop/explosion at the mouth of the rocket.
oxygen (H ₂)	The glowing splint bursts into flame (relights); pure oxygen supports combustion strongly.

Prediction:

Q6. Using your observations, make a prediction for what ratio of gases you think will be best to propel a rocket the furthest. See the table on the next page with the ratios you will be using.

Predicted best ratio: 1 O₂ : 2 H₂

Reason why:

The best mixture is 2 volumes of hydrogen to 1 of oxygen (2H₂ + O₂ → 2H₂O) because this is the exact ratio in which they react completely, releasing the most energy.

Method PART 3:

Fill the rockets with different ratios of gases and test.

- k) Collect a rocket and fill it with water again.
- l) This time only fill the rocket with $\frac{1}{2}$ oxygen. Always fill with oxygen first.
- m) Quickly remove it and place it onto the hydrogen gas generator and displace the rest of the water.
- n) When not collecting gas, ensure your finger is *always covering the hole* to seal your mixture of gases inside the rocket.
- o) At the launch site quickly place the pipette bulb over the spark generator and press launch!
- p) Measure the distance that the rocket travelled (in cm) and record it in the table below.
- q) Start again, but this time fill the rocket with the other ratios in the table below recording your data as you go.
- r) If you have time, repeat the whole experiment and calculate an average.

Note: If the reaction in one of the gas generators slows down so much that it is no longer useful, fill the second gas generating tube with liquid (either HCl or H_2O_2 , as appropriate) and use it instead.

Results:

Oxygen to hydrogen ratio $\text{O}_2 : \text{H}_2$	Distance travelled by rocket (cm)			
	Trial 1	Trial 2	Trial 3	Average
1 : 5	Record the measured distance for Trial 1 (cm)	Record the measured distance for Trial 2 (cm)	Record the measured distance for Trial 3 (cm)	Average of trials 1-3 (cm)
2 : 4	Record the measured distance for Trial 1 (cm)	Record the measured distance for Trial 2 (cm)	Record the measured distance for Trial 3 (cm)	Average of trials 1-3 (cm)
3 : 3	Record the measured distance for Trial 1 (cm)	Record the measured distance for Trial 2 (cm)	Record the measured distance for Trial 3 (cm)	Average of trials 1-3 (cm)
4 : 2	Record the measured distance for Trial 1 (cm)	Record the measured distance for Trial 2 (cm)	Record the measured distance for Trial 3 (cm)	Average of trials 1-3 (cm)
5 : 1	Record the measured distance for Trial 1 (cm)	Record the measured distance for Trial 2 (cm)	Record the measured distance for Trial 3 (cm)	Average of trials 1-3 (cm)

Also record your **qualitative observations**. For example, which ratio made the loudest bang? Were there any flames? Did the rocket bounce funny or sometimes not work at all?

The 2:4 ratio made the loudest bang and the brightest flash; rockets with too much oxygen (5:1) often failed to launch or just bounced, and the 1:5 mixture was quiet and slow.

Q7. Draw a bar graph to show the average distance travelled for each ratio of gas

Bar chart: x-axis = oxygen:hydrogen ratio (1:5, 2:4, 3:3, 4:2, 5:1), y-axis = average distance travelled (cm); tallest bar at the 2:4 ratio.

Conclusion:

Q7. Write a balanced chemical equation for the combustion reaction of hydrogen and oxygen. You may want to refer to the word equation in question 1.

Q8. Use the balanced chemical equation above to explain which rocket travelled the furthest distance.

The rocket with the mixture that reacted most vigorously released the most energy, so it travelled furthest. The 2:4 rocket. The equation shows 2 hydrogen molecules react with 1 oxygen molecule, i.e. $H_2:O_2 = 2:1$. 4:2 is the correct 2:1 hydrogen: oxygen mixture ($2H_2 + O_2 \rightarrow 2H_2O$). The same ratio, so both gases are used up completely and the most energy is released.

Evaluation:

Q9. What parts of your experiment worked well?

Measuring the volumes of gas and using the same rocket each time worked well; repeats gave similar distances.

The gas generators gave a steady supply of gas, the rockets filled easily by displacing the water, and repeating each ratio three times made the results more reliable.

Q10. What aspects of your experiment lacked accuracy? What could you do to improve the accuracy?

Volumes of gas and distances measured by eye were inaccurate. Measure gas with a gas syringe and distance with a metre rule.

Q11. What aspects of your experiment lacked precision? What could you do to improve the precision?

The distances varied between repeats. Control the launch angle, using marked angles and calculate the launch taking everything identical (same spark, launch angle and timing).

Extension:

Carry out some research about the fuels used in real space rockets. Are there any similarities to what you have done today? What are the main differences in terms of the chemical reaction taking place between your 'rocket' and real spaceships?

Real rockets burn liquid hydrogen with liquid oxygen (Space Shuttle) or kerosene with liquid oxygen. Similar: fuel (kerosene and liquid oxygen) contained in a pressurised tank and burn continuously for steady thrust, not more energy than our one-off hydrogen/oxygen explosion in a test tube.

Metals and Water

Metal	Observations when put in water
magnesium	Almost no visible reaction - a few tiny bubbles of hydrogen form very slowly.
zinc	No visible reaction with cold water.
lead	No visible reaction with cold water.
iron	No visible reaction with cold water (it rusts slowly in water and air).
copper	No visible reaction with cold water.

Note that most metals show no reaction with water. Or the reaction is so slow, it is not noticeable. We will leave these metals in water until the next lesson and look again.

More Reactive metals: Fill in your observations during/after demonstrations.

	Calcium	Lithium	Sodium	Potassium
Symbol		Li	Na	
Metal or Non-metal?		metal	metal	
Appearance		Soft, silvery-grey shiny metal that tarnishes in air	Soft, silvery-grey shiny metal that tarnishes in air	
More or less dense than water		Less dense than water - it floats	Less dense than water - it floats	
Method of storage		Stored under oil (so it cannot react with air or water)	Stored under oil (so it cannot react with air or water)	

	Calcium	Lithium	Sodium	Potassium
Reaction with water	Reacts steadily - bubbles of hydrogen are given off, the metal shrinks and the water turns cloudy white (calcium hydroxide).	Fizzes steadily, floating and moving on the surface, giving off bubbles of hydrogen as the metal shrinks.	Reacts vigorously - melts into a shiny ball, fizzes and whizzes across the surface, sometimes with a yellow flame.	Reacts very vigorously - it catches fire with a lilac flame and darts/whizzes across the surface.
Products of reaction with water	calcium hydroxide + hydrogen	lithium hydroxide + hydrogen	sodium hydroxide + hydrogen	potassium hydroxide + hydrogen

EQUATIONS

Complete the following word and chemical equations for some of the reactions you observed:

sodium + water → sodium hydroxide..... + hydrogen.....

.....Na +H₂O →NaOH +₂H₂

potassium + water → potassium hydroxide..... + hydrogen.....

.....K +H₂O →KOH +₂H₂

calcium + water → calcium hydroxide..... + hydrogen.....

.....Ca +H₂O →Ca(OH)₂ +₂H₂

Metals Reactions

Choose your answers from the words below. Each answer is used only once.

calcium copper iron lead magnesium potassium sodium

1. Give the name of:
 - a** two metals which float on water and react very quickly to form alkalis **potassium and sodium**
 - b** a metal which burns with a bright white flame and reacts slowly with cold water **magnesium**
 - c** a metal which goes rusty if you leave it in water **iron**
 - d** a metal which reacts quickly with water and makes the water go white **calcium**
 - e** a metal which is still used for piping because it does not react with water **copper**
 - f** a metal which used to be used for piping but is no longer used because of the risk of poisoning the water supply. **lead**

2. Look at the sketch of the Periodic Table.

Which section of the table includes:

- a** unreactive metals and non-metals **The right-hand side of the table (the unreactive metals and the non-metals, e.g. the noble gases).**
- b** the most reactive metals **The far left-hand column (Group 1, the alkali metals).**
- c** metals that are less reactive. **The central block of the table (the transition metals).**

3. Two of the metals in the list below react with water, giving off a gas and producing metal hydroxides. The other two metals do not react.

sodium lead copper calcium

The two most reactive metals in the list (highest in the reactivity series) react with water, giving hydrogen and a metal hydroxide; the two least reactive metals do not react.

- a Which two metals do *not* react? **lead and copper**
- b Write word equations for the reactions of the other two metals with water.
sodium + water → sodium hydroxide + hydrogen; calcium + water → calcium hydroxide + hydrogen

4. Carlton wrote in his exercise book:

The metals that react best with oxygen are the same as the ones which react best with water. If you put them in order of reactivity, the order is exactly the same. All the metals which burn also react with water.

Do you agree with Carlton or not? Explain your answer.

Do not agree with Carlton. The products of metal + water are a metal hydroxide and hydrogen gas (not a metal oxide), and the more reactive the metal the faster/more vigorous the reaction.

Metals and Steam

Some metals do not react with cold water but will react with **steam**. Suggest why

.....

.....

.....

Your teacher will demonstrate **magnesium** and **steam**. Describe your observations.

Observations:

The magnesium glowed and burnt brightly with a white flame when it met the steam.

A white solid (magnesium oxide) was left behind and hydrogen gas was given off.

.....

.....

Steam is at a much higher temperature than cold water, so the particles have more energy and more collisions have enough energy (activation energy) for the reaction to happen.

Complete the following **word** and **chemical equation** for the reaction of steam and magnesium

The magnesium glows/burns with a bright white light; a white solid (magnesium oxide) forms in the tube and hydrogen gas is given off, which burns with a squeaky pop.

magnesium + steam → magnesium oxide + hydrogen

.....Mg +H₂O →Mg(OH)₂ + **1**H₂

Draw and label the diagram/observations for this practical in the panel (no written answer required).

9Fa/3 Reactions with water

aluminium Al No reaction with cold or hot water. Will react with steam to produce aluminium oxide and hydrogen. 	magnesium Mg Very slow reaction with cold water. Slow reaction with hot water. Reacts readily with steam to form magnesium oxide and hydrogen. 
calcium Ca Reacts rapidly with cold water. Hydrogen gas is given off. The water turns milky white. 	potassium K  Violent reaction. Potassium floats on the surface of the water, melts and then catches fire. Burns with a lilac coloured flame. Hydrogen gas given off. 
copper Cu No reaction with cold or hot water. No reaction with steam. 	silver Ag No reaction with cold or hot water. No reaction with steam. 
gold Au No reaction with cold or hot water. No reaction with steam. 	sodium Na  Rapid reaction. Sodium floats on water, and moves around rapidly. Heat from the reaction melts the sodium. Hydrogen gas given off. 
iron Fe Iron will rust slowly in cold water. 	zinc Zn No reaction with cold or hot water. Will react slowly with steam to produce zinc oxide and hydrogen. 

Draw and label the diagram/observations for this practical in the panel (no written answer required).

9Fb/4 Reactions with oxygen

aluminium Al  No reaction when in block form unless heated very strongly indeed. Burns readily in powder form. 	magnesium Mg  Magnesium ribbon burns brightly when heated in a flame. Magnesium powder burns very rapidly with a white flash. 
calcium Ca  Calcium pieces burn strongly if heated in a flame for several minutes. 	potassium K  Melts very easily and then catches fire. Burns very rapidly with a lilac coloured flame. 
copper Cu Metal glows red when heated in a strong flame but does not burn. There is a black coating on the metal at the end. 	silver Ag No reaction in a flame. Silver will melt if it is heated to a high temperature, but it will not burn. Will react very slowly with the air to form silver oxide. 
gold Au No reaction. Gold will melt if it is heated to a high temperature, but it will not burn. It does not oxidise in the air. 	sodium Na  Melts easily and then sets on fire. Burns rapidly with a yellow/orange flame. 
iron Fe No reaction in block form. Fine wire or filings will sparkle when put in a flame. Iron will rust slowly in moist air. 	zinc Zn No reaction when in block form. Burns in powder form. 

Reaction of Metals and Acids Practical

Aim: Rank metals in order of reactivity based on their reactions with acid. Construct word equations and simple balanced equations for metal + acid reactions.

Planning

1. What factors should you keep the same to make it a fair test?

·

·

·

2. Why is it difficult in this case to make the test completely fair?

The same volume of dilute hydrochloric acid in each test tube.

The same concentration of acid and the same starting temperature.

Materials required:

- Calcium metal
- Copper pieces
- Magnesium ribbon
- Iron nails
- Zinc pieces
- Dilute hydrochloric acid
- Test tube rack
- 5 test tubes
- Wooden splint
- Lighter
- Goggles

Safety:

Do not touch the pieces of calcium. Your teacher will handle the calcium using forceps.

Wear eye protection

What to do:

Your teacher will add a piece of calcium to a test tube about 1/3 full with dilute hydrochloric acid. Note the results.

1. Fill a different test tube about 1/3 full with dilute hydrochloric acid.
2. Add a piece of one of the metals shown in the table below.
3. If any gas is given off, test it with a lighted splint.
4. Feel the tube to see if it is warm.
5. Look to see if the metal has reacted in the acid.
6. Record your results in the table.
7. Repeat the test with other metals.

Results :

Metal	Did you get bubbles?	Did the gas burn with a pop?	Did the metal react?	Did the tube get warm?
calcium	Yes - lots of bubbles	Yes - burned with a pop	Yes - the metal fizzed away	Yes - the tube got warm
copper	No bubbles	No gas given off	No - no reaction	No - stayed cold
magnesium	Yes - steady stream of bubbles	Yes - loud pop	Yes - the metal dissolved	Yes - got warm
iron	Yes - a few slow bubbles	Yes - small pop	Yes - reacted slowly	Yes - warmed slightly
zinc	Yes - steady bubbles	Yes - popped	Yes - dissolved slowly	Yes - got warm

Analysis of your results :

How many metals reacted? 4

How many did not react? 1

What is the name of the gas that is given off ? hydrogen

List the metals in order of reactivity, from the highest to the lowest.

- 1 calcium
- 2 magnesium
- 3 zinc
- 4 iron
- 5 copper

Write word equations for the reactions that have taken place.

calcium + hydrochloric acid · calcium chloride + hydrogen; magnesium + hydrochloric acid · magnesium chloride + hydrogen; zinc + hydrochloric acid · zinc chloride + hydrogen; iron + hydrochloric acid · iron chloride + hydrogen

More challenging:

Write balanced equations for each of the word equations you gave above.

$\text{Ca} + 2\text{HCl} \cdot \text{CaCl}_2 + \text{H}_2$; $\text{Mg} + 2\text{HCl} \cdot \text{MgCl}_2 + \text{H}_2$; $\text{Zn} + 2\text{HCl} \cdot \text{ZnCl}_2 + \text{H}_2$; $\text{Fe} + 2\text{HCl} \cdot \text{FeCl}_2 + \text{H}_2$

The formula for hydrochloric acid is HCl, Hydrogen gas is H₂ and magnesium chloride is MgCl₂. All the other salts have a similar formula to magnesium chloride.

Metals and Acids Formulae and Equations

- 1 The symbol equation for the reaction of zinc with sulfuric acid is:

- a How many atoms are there in a molecule of hydrogen gas? 2
- b Name one compound in this equation that does not contain a metal. sulfuric acid
- c What is the name of the compound with the formula ZnSO_4 ? zinc sulfate
- d This is a *balanced* equation. Explain the meaning of 'balanced' in terms of numbers of atoms. The number of atoms of each element is the same on both sides of the equation - no atoms are lost or created.
- e Write a similar balanced symbol equation for the reaction of magnesium with sulphuric acid. $\text{Mg} + \text{H}_2\text{SO}_4 \rightarrow \text{MgSO}_4 + \text{H}_2$

- 2 The formula of zinc chloride is ZnCl_2 . Here is an equation which shows the formulae of all the substances that take part in the reaction:

- a Write the formulae for:
- the two reactants Zn and HCl
 - the two products. ZnCl_2 and H_2
- b The equation above is not fully correct. It is not balanced. Explain why it is wrong.

The balanced equation is written like this:

It is not balanced: there is one chlorine atom on the left but two on the right (and one hydrogen atom on the left but two on the right).

- c This diagram illustrates the equation.

In the diagram, which symbol represents:

- i an atom of zinc the large single circle (the symbol for one zinc atom)
- ii an atom of hydrogen the small single circle (the symbol for one hydrogen atom)
- iii a molecule of hydrogen? two small circles joined together (the symbol for a hydrogen molecule, H₂)

d Kevin wrote that the correct symbol equation should be

Kevin's equation is balanced, but it is not correct. Explain why Kevin's equation is not correct. The formulae are wrong: hydrogen gas is H₂ (two atoms joined) and zinc chloride is ZnCl₂, so the correct equation is $\text{Zn} + 2\text{HCl} \rightarrow \text{ZnCl}_2 + \text{H}_2$.

3 Balance the following chemical reactions:

Metals and Acids Review and Application

1. When metals react with acids, a gas may be given off.

a Name the gas hydrogen

b How do we test for this gas? Put a lighted splint at the mouth of the test tube - the gas burns with a squeaky pop.

2. Complete the word equations for these reactions. Here is an example:

calcium + hydrochloric acid → calcium chloride + hydrogen

a calcium + nitric acid → calcium nitrate + hydrogen

b zinc + hydrochloric acid → zinc chloride + hydrogen

c magnesium + hydrochloric acid → magnesium chloride + hydrogen

d iron + sulphuric acid → iron sulphate + hydrogen

3. Put these formulae next to the correct acid in the table below.

Acid	Chemical formula
nitric	<u>HNO3</u>
sulphuric	<u>H2SO4</u>
hydrochloric	<u>HCl</u>

4. You have got some sulfuric acid that you need to store. You could store it in a metal can, a glass jar or a plastic bottle.

Suggest advantages and disadvantages for each type of container, and say which one you think would be the best to choose.

Advantages of a metal can It is strong and will not smash if it is dropped.

It is cheap, light and easy to be sealed tightly.

Use the glass jar or the plastic bottle - sulfuric acid would react with the metal can (metal + acid $\rightarrow$ salt + hydrogen).

Advantages of a glass jar Glass does not react with the acid, so the acid stays pure.

It is transparent, so you can see how much acid is inside.

Advantages of a plastic bottle Plastic is cheap, light and does not react with the acid.

It will not break or smash if it is knocked over.

Disadvantages of a metal can The acid reacts with the metal, so the can would corrode.

Metal ions would get into the acid and contaminate it.

Disadvantages of a glass jar Glass is brittle, so it breaks easily and is dangerous.

It is heavy and the sharp pieces could cut someone.

Disadvantages of a plastic bottle It is not as strong as glass and some acids may slowly attack the plastic.

It could split or leak if it is dropped.

Which would you choose? a plastic bottle

Why? It does not react with the acid and it will not smash if it is dropped.

Title: Making Salts

Salts are made when acids react with various substances such as alkalis, metals or alkaline solutions.

The name of the salt will depend upon the acid and the other substance in the reaction.

Here are some examples:

- sulfuric acid + copper oxide → copper sulfate
- hydrochloric acid + magnesium → magnesium chloride
- sulfuric acid + copper oxide → copper sulfate
- nitric acid + zinc oxide → zinc nitrate

Acid	Substance	Salt Formed
Hydrochloric	Copper Oxide	copper chloride
Hydrochloric	Calcium Carbonate	calcium chloride
sulfuric Acid	Magnesium Oxide	magnesium sulfate
sulfuric Acid	Zinc	zinc sulfate
Nitric Acid	Magnesium	magnesium nitrate
Nitric Acid	Sodium Hydrogen Carbonate	sodium nitrate

Conclusion:

1. When a substance reacts with hydrochloric acid a chloride is formed.
2. When a substance reacts with sulfuric acid a sulfate is formed.
3. When a substance reacts with nitric acid a nitrate is formed.
4. The other products in the reactions are water, carbon dioxide and hydrogen depending on the substance added to the acid.

Title: Making Copper Sulfate Crystals

Aim: To produce pure, dry crystals of copper sulfate by reacting a base (copper oxide) and sulfuric acid

Materials Required

Dilute (0.5M) sulfuric acid
Copper oxide
Filter paper, filter funnel
50cm³ measuring cylinder
250cm³ beaker
Glass rod and spatula
250cm³ conical flask
Evaporating basin
Tripod, gauze, bunsen
Fireproof mat

Space for your own labelled diagram/notes of the apparatus and safety points (no written answer required).

Safety.
Wear safety goggles.
Be careful when heating the acid using the bunsen.

Heat the acid for just 1 minute on a safety flame.

Methods

1. Put 50cm³ of *dilute sulfuric acid* in a 250cm³ beaker using a measuring cylinder.
2. Very carefully heat the acid using a Bunsen for 1 minute.
3. Turn off the Bunsen burner.
4. Add the copper oxide base to the acid *one spatula measure at a time*, until no more reacts. **Stir** the mixture with a glass rod.
5. **Filter** the mixture. Collect the liquid (**filtrate**) in a conical flask.
6. Put the liquid in an evaporating dish. You should only fill this up to $\frac{2}{3}$ full. Carefully **evaporate** the filtrate to *half its original volume* OR until crystals are seen forming at the edge of the solution (Heat gently to stop the solution from spitting). Keep adding any more solution until you have a saturated solution.
7. Leave the basin to *cool*. The *crystals* of salt should form slowly. This may take a few days and is best left on the window sill in the lab. Please label your evaporating basin.
8. After the crystals have formed, **decant** the excess solution and **blot** the crystals **dry** on a paper towel.

Considering Your Results

Draw 2D pencil-and-ruler diagrams of each stage: acid in beaker; adding copper oxide and stirring; filtering; evaporating the filtrate; crystals forming as it cools; drying the crystals.

Pictures of the different stages of preparation are shown. Draw **diagrams** of each stage - use a pencil & ruler and draw in 2D.

Describe the colour, shape and size of the crystals. Are they transparent and clear or dull and opaque? This will tell you how pure the salt crystals are.

The crystals are blue, small and regular (rhombic/diamond-shaped). They are transparent and shiny (clear, not dull), which shows the salt is pure.

Extension: How is the size of the crystals related to the speed of evaporation?

The slower the evaporation, the larger the crystals, because the ions have more time to arrange themselves into a regular lattice. Fast evaporation gives small crystals.

9C 8b

Questions on Acid Base Salt Preparation

Copper sulfate crystals were made by adding **excess base** to an **acid**.

Bases are **metal oxide** solids (e.g. copper oxide, CuO)

Q1:

1) Name and give the *formula* of the **acid** used to make **copper sulfate** crystals.

name: sulfuric acid **formula:** H₂SO₄

ii) Give the name and formula of the **base** used to make these **salt** crystals.

name: copper oxide *formula:* CuO

Complete the general equation that describes this reaction.

Write a **word** and **chemical equation** for this reaction

copper oxide + sulfuric acid → copper sulfate + water

$$\text{CuO} + \text{H}_2\text{SO}_4 \rightarrow \text{CuSO}_4 + \text{H}_2\text{O}$$

salt

During this reaction, the acid becomes neutral. How could this be tested?

Dip a clean glass rod in the solution and touch it on universal indicator paper - it should turn green (pH 7, neutral).

When an acid is made neutral, what type of reaction is this called? **neutralisation**

Why was **excess** copper oxide used in this reaction?

To make sure all the acid is used up (reacted), so the solution becomes neutral and no acid is left in the crystals.

How was the excess copper oxide removed?

by filtration (the unreacted copper oxide stayed in the filter paper)

Why was the solution only partially evaporated?

So that the solution becomes saturated and crystals form as it cools; evaporating it all away would leave a powder, not crystals.

Describe how **dry** crystals are obtained from the cooled solution.

Decant (pour off) the remaining solution, then blot the crystals dry on filter paper/paper towel.

Alkalis are soluble bases.

Alkalis are soluble **metal hydroxide** solutions. (e.g. sodium hydroxide NaOH).

Alkalis react in the same way as **bases**.

j) Complete the general equation that describes a reaction between an acid and an alkali.

k) Are alkali's solids or solutions? **solutions**

Are alkali metal oxides or metal hydroxides? **metal hydroxides**

Complete this equation about how an alkali and an acid react.

The acid is made into a neutral substance during this reaction. If the salt were tested with U.I paper, what colour should it be? **green (the salt solution is neutral, pH 7)**

Q2. Give the word equations and symbol equations for the following acid base reactions.
(you will need these formula **ZnSO₄** and **KNO₃**)

a)i) Sulfuric acid + Zinc oxide **zinc sulfate + water**

a)ii) H_2SO_4 + ZnO **$\text{ZnSO}_4 + \text{H}_2\text{O}$**

b)i) Nitric acid + potassium hydroxide. **potassium nitrate + water**

b)ii) HNO_3 + KOH **$\text{KNO}_3 + \text{H}_2\text{O}$**

EXTENSION:

The crystals of copper sulfate contain **water of crystallisation**.

This is water which is *chemically joined* to the crystals. The crystals are said to be **hydrated**.

If **hydrated copper sulfate** crystals are heated they give off steam and **anhydrous copper sulfate** is formed.

Write the formula for **hydrated** copper sulfate. **$\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$**

Write the formula for **anhydrous** copper sulfate. **CuSO_4**

Space for notes/diagrams about salt preparation

1. Measure 50 cm³ of dilute sulfuric acid into a beaker.

2. Warm the acid gently on a safety flame for 1 minute, then turn off the Bunsen.

3. Add copper oxide a spatula at a time, stirring with a glass rod, until no more dissolves.

4. The excess black copper oxide sinks to the bottom - the acid is now neutralised.

5. Filter the mixture to remove the excess copper oxide; keep the blue filtrate.

6. Evaporate the filtrate gently to about half its volume (or until crystals appear at the edge).

7. Leave the saturated solution to cool slowly - blue crystals of copper sulfate form.

8. Decant the cold solution and blot the crystals dry on filter paper.

acid + metal oxide → salt + water (a neutralisation reaction)

The crystals are hydrated: $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ (blue). Heating them gives white anhydrous CuSO_4 + water.

Diagram: filter funnel with folded filter paper in a conical flask, mixture poured down a glass rod.

Never evaporate to dryness - it makes a powder, not crystals.

Displacement Reactions

Aim: Deduce the order of reactivity of several metals from results of displacement reactions.
Construct word equations for displacement reactions.

Information

A **displacement reaction** is one where a **more reactive metal** will displace a **less reactive metal** from its compounds

Planning

a Choose a colour, and underline the four elements on the results table overleaf.

b Choose a different colour, and underline the four compounds.

c Fill in the key by your table

- Underline the four elements in one colour: copper, zinc, iron, magnesium.
- Underline the four compounds in a different colour: copper sulfate, zinc sulfate, iron sulfate, magnesium sulfate.

Materials required:

- Copper foil
- Magnesium ribbon
- Iron nails
- Zinc foil

Solutions of:

- Copper sulfate
- Magnesium sulfate
- Iron(III)sulfate
- Zinc sulfate
- Spotting tile

· Key: colour 1 = elements (copper, zinc, iron, magnesium); colour 2 = compounds (the sulfate solutions).

Safety:

Wear eye protection

What to do:

- 1 Fill 3 wells on a spotting tile (dimple tile) with copper sulfate solution.
- 2 Add 1 piece of zinc to one, an iron nail to the second and 1 piece of magnesium to the third.
- 3 Leave the solutions for several minutes. Check to see if there is any reaction. Look for:
 - colour changes on the surface of the metal
 - colour changes in the solution
 - bubbles of gas given off
- 4 Write your results in the table. Please write the ORIGINAL colour of each metal and each solution above the name for each substance.
- 5 Repeat the experiment with the other solutions. You may take a photo of your results.

Results :

• Full grid (metal x solution): copper - no reaction with any solution. Zinc and iron - react with copper sulfate only. Magnesium - reacts with copper sulfate, zinc sulfate and iron sulfate (not magnesium sulfate).

	copper sulfate	zinc sulfate	Iron sulfate	magnesium sulfate
copper		No reaction - the copper piece does not change (copper is less reactive than copper).		
zinc		Reacts - the zinc becomes coated with a pink/brown layer of copper and the blue colour of the solution fades.		
iron		Reacts - a brown/pink layer of copper forms on the iron nail and the blue solution turns pale green.		
magnesium		Reacts quickly - copper is deposited on the magnesium and the blue colour disappears; the tube gets warm.		

Key

elements

compounds

Order of reactivity of metals:

1 magnesium

2 zinc

3 iron

4 copper

Analysis

1. How does the list of metals compare with the list of compounds?
They are in the opposite (reverse) order - the most reactive metal is the one whose compound is hardest to displace, so the metal list is the reverse of the compound list.
2. Here is a word equation for the reaction of lead with copper sulfate:

Write word equations **for the reactions that took place** in your experiments
zinc + copper sulfate · zinc sulfate + copper; iron + copper sulfate · iron sulfate + copper;
magnesium + copper sulfate · magnesium sulfate + copper; magnesium + zinc sulfate ·
magnesium sulfate + zinc; magnesium + iron sulfate · magnesium sulfate + iron

Reactivity Series of Metals

Aim: Recall the reactivity series of metals : *potassium, sodium, lithium, calcium, magnesium, aluminium, zinc, iron, (hydrogen), copper, silver and gold.*

Remembering the Reactivity Series

Find a way of remembering the Reactivity Series. Some ideas are given below:

1. Look for Patterns – colour all the Group 1 metals in red, group 2 metals in green, group 3 metals in yellow and transition metals in blue:

Potassium	K
Sodium	Na
Lithium	Li
Calcium	Ca
Magnesium	Mg
Aluminium	Al
Zinc	Zn
Iron	Fe
(Hydrogen)	(H) Hhydrogen is not a metal but sometimes reacts like one
Copper	Cu
Silver	Ag
Gold	Au

2. Make up a rhyme (or mnemonic). A suggestion is given below:

Potassium	Peter
Sodium	Smith
Lithium	Loves
Calcium	Catching
Magnesium	Monkeys
Aluminium	And
Zinc	Zebras
Iron	If
(Hydrogen)	His
Copper	Catch
Silver	Smells
Gold	Good

See if you can do better! Try making a rhyme of your own.

Share rhymes and vote for the best one – adopt it as a class mnemonic!

e.g. "Please Send Lucy's Cat More Apples, Zebras If Harry Can't Sit Gloomily."

Displacement Equations and Applications

1. Complete the following word equations and then use the formula given below to write balanced equations for these reactions. An example is done for you.

e.g.

magnesium + copper sulfate → magnesium sulfate + copper

a) zinc + iron chloride → zinc chloride + iron; $\text{Zn} + \text{FeCl}_2 \rightarrow \text{ZnCl}_2 + \text{Fe}$

b) magnesium + copper oxide → magnesium oxide + copper; $\text{Mg} + \text{CuO} \rightarrow \text{MgO} + \text{Cu}$

2. Explain what happens in a **displacement** reaction?

.....
A more reactive metal takes the place of (displaces) a less reactive metal in its compound, forming a new compound and leaving the less reactive metal behind.

3. Use the Reactivity Series to help you to decide which of the pairs below will react.

IF THEY DO REACT then complete the word equation, otherwise write 'no reaction'

zinc + copper oxide → zinc oxide + copper (zinc is more reactive than copper, so it displaces it)

iron + magnesium oxide →
no reaction (iron is less reactive than magnesium, so it cannot displace it)

magnesium + sulfuric acid → magnesium sulfate + hydrogen

copper + silver nitrate →
copper nitrate + silver (copper is more reactive than silver)

copper + magnesium chloride → no reaction (copper is less reactive than magnesium, so it cannot displace it)

4. You have 3 unknown metals A, B and C. You know that C displaces B from its oxide when heated. However, there is no reaction when C is heated with the oxide of A.

Rank the 3 metals in order of reactivity (most reactive first). Explain how you reached your decision.

Most reactive first: A, C, B. C displaces B, so C is more reactive than B. C does not displace A, so A is more reactive than C. Therefore $A > C > B$.

Precipitation Reactions

A precipitation reaction occurs with lead nitrate solution and potassium iodide solution.

What is a precipitation reaction? A reaction in which two solutions are mixed and an insoluble solid (a precipitate) is formed.

The reaction between lead nitrate and potassium iodide is also a displacement reaction. Write the word equation for this reaction.

Now balance the chemical equation for this reaction.

lead nitrate + potassium iodide → lead iodide + potassium nitrate

Practical

1. Add the two solutions together in a test tube. (Do this *slowly* and how your teacher demonstrated the first experiment.)
2. Filter your mixture to obtain the insoluble salt.
3. Write a word and chemical equation.
4. Wash your salt with distilled water to remove other chemicals.
5. Once the filtering is complete, unfold your filter paper and allow the salt to dry.

Draw labelled apparatus of how you obtained your salt via filtration

· Draw: filter funnel with folded filter paper clamped over a conical flask, mixture poured down a glass rod; yellow lead iodide trapped in the paper; filtrate collects in the flask.

Extension:

Sodium chloride (common table salt) has some well known uses such as flavouring and preserving food. However, there are many other salts with many different uses. Research some different salts and give their uses in the table below

· Uses: copper sulfate - fungicide/algaeicide and in farming; potassium nitrate - fertiliser and gunpowder; calcium carbonate - making cement/glass and as an antacid

Name of salt	Use
copper sulfate	
potassium nitrate	
calcium carbonate	

Precipitation Reaction Equations

You do **not** need to know any of the following reactions off by heart. However, you should be able to do the following:

- 1) Read the word equation
- 2) Balance the chemical equation (if it is already balanced, say so)
- 3) Use the information to highlight the precipitate.

sodium hydroxide + silver nitrate → sodium nitrate + silver hydroxide

The precipitate of silver hydroxide is brown.

Already balanced - no numbers need to be added (every formula has a coefficient of 1).

sodium hydroxide + copper sulfate → sodium sulfate + copper hydroxide

A blue gelatinous precipitate of copper hydroxide is produced.

potassium iodide + mercury nitrate → mercury iodide + potassium nitrate

A bright orange precipitate of mercury iodide is produced.

potassium iodide + silver nitrate → potassium nitrate + silver iodide

A yellow white precipitate of silver iodide, AgI is produced.

Already balanced - no numbers need to be added (every formula has a coefficient of 1).

sodium chloride + silver nitrate → sodium nitrate + silver chloride

A creamy silver chloride precipitate is formed.

Already balanced - no numbers need to be added (every formula has a coefficient of 1).

mercury nitrate + potassium fluoride → mercury fluoride + potassium nitrate

An orange brown precipitate of mercury fluoride, HgF₃ is produced.

copper sulfate + potassium iodide → copper iodide + potassium sulfate

An olive green precipitate of copper iodide is produced.

Thermal decomposition of metal carbonates

INTRODUCTION:

Some metal carbonates undergo thermal decomposition (the breakdown of a compound when it is heated). One such example is copper carbonate. In this practical, you are going to observe what happens when copper carbonate decomposes.

PROCEDURE:

1. Set up the apparatus as demonstrated to you by your teacher. Draw a diagram of it here →
2. Add a small pile of copper carbonate to the boiling tube.
3. Heat the metal carbonate strongly; try not to move any of the apparatus.
4. As soon as you start heating, hold a test tube of limewater in position and once cloudy, remove the test tube, **but do NOT stop heating**.
5. Carefully observe the carbonate to see if you can see any changes in appearance.
6. Check there is no more liquid in the delivery tube. Only once the delivery tube is empty, turn off the heat.

· Diagram: boiling tube of copper carbonate clamped and heated strongly, with a delivery tube leading the gas into a test tube of limewater.

Experiment set up

QUESTIONS:

- a) Give the word equation for the thermal decomposition of copper carbonate.

copper carbonate → copper oxide + carbon dioxide

- b) Give the balanced chemical equation for the thermal decomposition of copper carbonate (CuCO_3) to make copper oxide (CuO) and carbon dioxide.

$\text{CuCO}_3 \rightarrow \text{CuO} + \text{CO}_2$ (already balanced)

- c) What colour change did copper carbonate show when it decomposed?

It changed from green to black.

- d) How do you know what gas was made?

The limewater turned cloudy (milky), which is the test for carbon dioxide.

- e) Limestone is mainly made up of calcium carbonate. This metal carbonate also decomposes when heated: write a word equation for this reaction.

calcium carbonate → calcium oxide + carbon dioxide

Introduction to Electrolysis

Your teacher will demonstrate the electrolysis of water using the Hoffman voltameter:

Write a word and balanced chemical equation for the reaction that takes place when water is electrolysed

Word equation: water -> hydrogen + oxygen

Chemical equation: $2\text{H}_2\text{O} \rightarrow 2\text{H}_2 + \text{O}_2$

What gas is produced at the positive electrode (anode)? oxygen

What gas is produced at the negative electrode (cathode)? hydrogen

What is electrolysis? The breakdown of an ionic compound (dissolved in water or molten) into its elements using electricity.

Fill in this table with the tests for gases:

Gas	Chemical Test	Positive Result
Oxygen (O_2)	Glowing splint	The splint relights (burns brightly)
hydrogen (H_2)	Burning splint	A squeaky 'pop'
chlorine (Cl_2)	Damp universal indicator paper (or damp litmus paper)	The paper is bleached white

Electrolysis of copper chloride solution

Instructions for Practical:

1. Build a circuit and check that it is working (the bulb should light when you touch the electrodes together). Once it is working, turn the power off.
2. Fill a small beaker with *about* 50 cm³ of copper chloride (CuCl₂) solution and set up the experiment as shown on the right
3. Insert the electrodes into the solution and turn on the power for 2-3 minutes. Observe.
4. Hold some damp UI paper above the electrode that is bubbling to test for chlorine.
5. Turn the power off and pull out the electrodes. Note down what you can see at each electrode.

Results:

Bubbles of gas given off at the positive electrode (anode). Observations at the positive electrode (anode): electrode, damp universal indicator paper is bleached (no chlorine).	
A pink-brown solid (copper) is deposited on the negative electrode (cathode). Observations at the negative electrode (cathode):	

Conclusion:

Write a word and chemical equation for the electrolysis of copper chloride (CuCl₂) solution

Word equation: copper chloride -> copper + chlorine

Chemical equation: CuCl₂ -> Cu + Cl₂

Give some uses for electrolysis: Extracting reactive metals such as aluminium from their ores.

Purifying copper.

Electroplating - coating objects with a thin layer of metal, e.g. silver plating cutlery.

Electrolysis of Aqueous Solutions

A student carried out an investigation into the electrolysis of sodium chloride.

The student placed solid sodium chloride into a beaker and inserted two graphite electrodes connected to a power supply. When the power supply was switched on, nothing appeared to happen.

1. Why did this experiment **not** work?

Tick **one** box.

Electrolysis is slow and does not start straight away. ☐

Solid sodium chloride does not conduct electricity. ☒

The voltage of the power supply was too high. ☐

The liquid contained no free ions (it was not an electrolyte), so it did not conduct electricity and no reaction happened.

The student then dissolved the sodium chloride in water.

Figure 1 shows the apparatus used in the electrolysis of sodium chloride solution, NaCl(aq).

2. The electrodes are made of graphite. Why is graphite a suitable material for the electrodes?

Tick **two** boxes.

Graphite has a high melting point. ☐

Graphite is a good conductor of electricity. ☒

Graphite is slippery. ☐

Graphite is unreactive. ☒

Graphite conducts electricity well and is unreactive (inert), so it does not react with the electrolyte.

The student observed that bubbles of gas were produced at both the positive and the negative electrodes.

The gas produced at the negative electrode is hydrogen.

3. Why are hydrogen ions present in sodium chloride solution, NaCl(aq)?

Tick **one** box.

Chloride ions are turned into hydrogen ions during electrolysis. ☐

Hydrogen from the air dissolves in the sodium chloride solution. ☐

Water molecules are split into hydrogen ions and hydroxide ions. ☒

Water ionises slightly: $\text{H}_2\text{O} \rightleftharpoons \text{H}^+ + \text{OH}^-$, so hydrogen ions are always present in any aqueous solution.

4. Explain why hydrogen gas is produced at the negative electrode and **not** sodium metal.

Sodium is more reactive than hydrogen, so the hydrogen ions are discharged in preference to the sodium ions, which stay in solution.

The students carried out another investigation to test the following hypothesis.

'In the electrolysis of salt solutions, oxygen is always produced at the positive electrode unless a halogen is present.'

5. Complete the table below to predict the name of the product that will form at each electrode during the electrolysis of the salt solutions named.

(cathode (negative) hydrogen or oxygen, unless the solution contains a halogen)

Salt Solution	Product Formed at the Positive Electrode (Anode)	Product Formed at the Negative Electrode (Cathode)
copper sulfate		
oxygen silver nitrate	copper	
oxygen zinc chloride	silver	

Summary Sheets - Acids, Bases and Indicators

Acids and alkalis

Indicators..... are coloured dyes which often come from plants such as red cabbage and beetroot.

Acids make indicators change colour. **Litmus** is an indicator which turns **red**..... in acids. Common acids include **vinegar**..... and **lemon**..... **juice**.....

Alkalis have a different effect on indicators to acids. Litmus turns **blue**..... in alkalis.

The strengths of acids and alkalis can be measured on the **pH scale**, which runs from 1 to 14. pH numbers **1 to 6.9** are acids, **7** is neutral, and **7.1 to 14** are alkalis. You can find out the pH number using a **universal**..... **indicator**....., or by using a **pH meter**.

Strong acid			Weak acid			neutral	Weak alkali			Strong alkali			
1	2	3	4	5	6	7	8	9	10	11	12	13	14

stomach
Acid

vinegar

skin

pure
water

indigestion
powders

washing
powder

oven
cleaner

lemon
Juice

fizzy
drinks

milk

blood

toothpaste

Metals and acids

Many metals react with acids. Some unreactive metals will only react very slowly with strong acids, some will not react at all. Some metals are more reactive and explode when added to acid.

When a metal reacts with an acid, **hydrogen**..... gas is given off. The reaction also produces a compound called a **salt**.

There are three main types of **salt**:

Chlorides are made when **hydrochloric**..... acid is used.

Sulfates are made when **sulfuric**..... acid is used.

Nitrates are made when **nitric**..... acid is used.

We can test for **hydrogen** by putting a **burning**..... **splint**..... into a test tube of gas. If hydrogen is present, it will explode with a **squeaky 'pop'**.

KEY WORDS: red, vinegar, indicators, universal indicator, lemon juice, blue, hydrogen, burning splint, hydrochloric, nitric, sulfuric,

The general equation is:

For example:

Bases

Bases are compounds which react with acids. All **metal oxides**, **metal hydroxides** and **metal carbonates** are bases. Bases which dissolve in water are called **alkalis** (e.g. sodium hydroxide).

Metal oxides and hydroxides and acids

A metal oxide or a metal hydroxide reacts with an acid to form water and a salt. This reaction is called **neutralisation**.

The general equation is:

For example:

We can check to see if neutralisation has occurred using universal indicator. The pH of the solution gets closer to neutral (pH7).

Metal carbonates and acids

A metal carbonate will also neutralise an acid. This time the products are a salt, carbon dioxide and water.

The general equation is:

For example:

We can test for **carbon dioxide** using **limewater**. Limewater goes milky if carbon dioxide is bubbled through it.

Some rocks, like **limestone** and **marble**, contain calcium carbonate. The rock fizzes when an acid is added and some of the rock is worn away. The rock is **weathered**.

KEY WORDS: neutralisation, copper, sulfate, zinc, limewater, hydrogen, carbon dioxide, limestone, marble

Preparation of soluble salts

Dry crystals of **soluble salts** can be prepared by reacting an acid with a metal, metal oxide or metal carbonate:

1. Measure out 25cm³ of acid using a **measuring**..... **cylinder**.....
2. Add excess solid to the acid and stir
3. **Filter**..... off the excess solid
4. Pour the filtrate into an **evaporating**..... basin
5. Heat to partially **evaporate**..... the solution
6. Leave the solution to **cool**..... and **crystallise**.....
7. Decant the excess solution and blot the crystals dry on a paper towel

Preparation of insoluble salts via precipitation reactions

1. Add the two solutions together in a **test**..... **tube**.....
2. **Filter**..... the mixture to obtain the insoluble salt.
3. **Wash**..... the salt with **distilled**..... water to remove other chemicals.
4. Allow the salt to dry and **crystallise**.....

KEY WORDS:

You can use these words, once, more than once or not at all.

measuring cylinder test tube filter distilled evaporate
wash crystallise cool evaporating

Acids & Salts Revision Questions

1. Give an example of:

- a) a strong acid ~~b) hydrochloric acid (HCl)~~ ~~c) acetic acid (CH_3COOH)~~ a weak acid
- c) a strong base ~~d) sodium hydroxide (NaOH)~~ ~~e) ammonia (NH_3)~~ a weak base

2. Complete the last column of the table to state whether the following substances are strongly acidic; weakly acidic; neutral; weakly basic or strongly basic. The first one has been done for you:

Substance	pH	Description
hydrochloric acid	1.0	strong acid
gastric juice	1.2	strongly acidic
ammonia	11.0	strongly basic
egg	7.8	weakly basic
Rain water	6.5	weakly acidic
apples	3.0	strongly acidic
milk	6.8	weakly acidic
tears	7.4	weakly basic
oven cleaner	13.8	strongly basic
human saliva	6.4	weakly acidic
human blood	7.4	weakly basic

3. In this topic you made different salts. Salts are made when an acid is **neutralised** by a base or when an acid reacts with a metal or a carbonate. Complete the following by filling in the blank spaces and by naming the compounds.

acid + base $\rightarrow$ salt + water; acid + metal $\rightarrow$ salt + hydrogen; acid + carbonate $\rightarrow$ salt + water + carbon dioxide.

Sulfuric acid (formula H_2SO_4) forms a salt called **sulfates**

Hydrochloric acid (formula HCl) forms salts called **chlorides**

Nitric acid(formula HNO_3) forms salts called nitrates

4. Look at the reactivity series on the right.

Metals above hydrogen in the reactivity series react with acids.

Complete the following word equations by writing the names of the substances in the appropriate place.

Metals above hydrogen in the reactivity series (e.g. potassium, sodium, calcium, magnesium, zinc, iron) react with acids; those below (copper, silver, gold) do not.

Reactivity Series of Metals

Potassium	most reactive
Sodium	
Calcium	
Magnesium	
Aluminium	
<u>Carbon</u>	
Zinc	
Iron	
Tin	
Lead	
<u>Hydrogen</u>	
Copper	
Silver	
Gold	
Platinum	least reactive

(Elements underlined, though non-metals, have been included for comparison)

5. Bases react with acids as follows:

Complete the following word equations:

6. Metal carbonates react with acids as follows:

Complete the following word equations:

7. Alkalis are soluble bases and these react with acids in a similar way to bases:

Complete the following word equation:

8. Hydrochloric acid is a strong acid.

(a) Winston used universal indicator solution to find the pH of some hydrochloric acid.

(i) Suggest the **colour** of the universal indicator in the hydrochloric acid. ~~red~~.....

(ii) Suggest the **pH** of the hydrochloric acid. ~~1 (a strong acid has a pH of about 0.2)~~.....

9. (a) Neutral litmus paper is purple in neutral solutions, red in acids & blue in alkalis.

Use this information to answer the questions.

(i) A piece of neutral litmus paper turned red in some grapefruit juice. What does this show about the grapefruit juice?

~~The grapefruit juice is acidic (it contains an acid)~~.....

(ii) Gwen added drops of sodium hydroxide solution to the grapefruit juice. The litmus paper soon turned blue. What does the blue colour show about the sodium hydroxide solution?

~~Sodium hydroxide solution is an alkali (alkaline)~~.....

(b) What name is given to the reaction between an acid and an alkali? Circle the correct answer

distillation neutralisation precipitation separation

10. In an experiment, Molly put two beakers on a balance. One contained 20 cm³ of hydrochloric acid. The other contained 5 g of sodium carbonate. She poured the acid onto the sodium carbonate. They reacted.

(a) Complete the word equation with the names of the **three** products.

sodium + hydrochloric → ~~sodium chloride~~..... + ~~carbon dioxide~~..... + ~~water~~.....
carbonate acid

(b) Balance the chemical equation:

- (c) The total mass at the start was 149.0 g. When the reaction stopped, the reading on the balance was 147.0 g. Why was there a loss of mass in this reaction?

~~Carbon dioxide gas was given off, so it escaped from the beaker into the air.~~.....

- (d) When the reaction stopped, Molly tested the contents of the beaker with universal indicator paper. The sodium carbonate had neutralised the acid. What is the colour of universal indicator paper in a neutral solution?

~~green~~.....

11. A student tried to make some magnesium sulfate (MgSO_4). Excess magnesium was added to dilute sulfuric acid (H_2SO_4). During this reaction fizzing was observed due to the production of a gas called hydrogen (H_2).

- (i) Is the equation for this reaction naturally balanced, or do numbers need to be added?

The equation is naturally balanced - numbers do not need to be added, every formula has a coefficient of 1.

- (ii) At the end of the reaction the solution remaining was filtered.
Why was the solution filtered?

~~To remove the excess (unreacted) magnesium metal from the solution.~~.....

- (iii) The filtered solution was left in a warm place. Explain why the filtered solution was left in a warm place.

~~So the water evaporates slowly, allowing crystals of magnesium sulfate to form.~~.....

.....

12. A student investigated the reaction between magnesium and hydrochloric acid.

(a) Give **two** observations the student could make during the reaction.

- 1 Bubbles of gas (fizzing) are given off - hydrogen is produced.
- 2 The magnesium dissolves/shrinks and the mixture gets warm.

(b) Write a word equation for this reaction

magnesium + hydrochloric acid → magnesium chloride + hydrogen

(c) The student investigated how the rate of this reaction changed when the concentration of hydrochloric acid was changed.

Write a plan the student could use.

In your plan you should:

- describe how you would carry out the investigation and make it a fair test (make it clear which variables you change, measure and control)
- describe the measurements you would make (ie give the method)

Change the concentration of the acid (1, 2 and 3 mol/dm³) and keep the volume of acid, the mass of

magnesium and the temperature the same. 10 seconds with a gas syringe, or time how long the magnesium takes to dissolve.

As the concentration of the acid increases, the rate of the reaction increases.

A higher concentration means more acid particles in the same volume, so collisions are more frequent.

On a graph the line is steeper and the same volume of gas is produced in less time.

Doubling the concentration roughly doubles the rate of reaction.

Quick Quiz: Types of Reaction

- 1 The gas in the air that reacts with metals most easily is:
A argon. B carbon dioxide. C nitrogen. D oxygen.
- 2 A metal that does not react with the air is:
A calcium. B gold. C iron. D magnesium.
- 3 The gas which is given off when metals react with water is:
A carbon dioxide. B hydrogen. C oxygen. D nitrogen.
- 4 Sodium reacts with water to form:
A sodium chloride.
B sodium oxide.
C sodium hydroxide.
D sodium carbonate.
5. The gas which is given off when metals react with acids is:
A carbon dioxide. B hydrogen. C oxygen. D nitrogen.
6. When magnesium reacts with sulfuric acid, it forms:
A magnesium oxide.
B magnesium chloride.
C magnesium sulfate.
D magnesium carbonate.
- Magnesium sulfate - magnesium reacts with sulfuric acid to give magnesium sulfate and hydrogen, not an oxide.
- 7 Choose the correct statement to complete this word equation:
zinc + sulfuric acid →
A zinc + sulfur + acid
B zinc hydrate + sulfur
C zinc sulfate + hydrogen
D zinc hydroxide + hydrogen
8. Iron is more reactive than copper. If a piece of iron is put into copper sulfate solution, what would you see?
A Brown copper would appear on the iron.
B Blue copper would appear on the iron.
C Nothing would happen.
D the iron would dissolve completely.

- 9 Zinc is more reactive than tin. It will displace tin from a compound. Choose the correct statement to complete this word equation:
- zinc + tin sulfate $\rightarrow$
- A zinc + tin sulfate
B zinc + zinc sulfate
C tin + zinc sulfate
D tin + zinc chloride
- 10 Copper is more reactive than silver. Iron is more reactive than copper. This means that:
- A copper will react with iron nitrate solution.
B silver will react with iron nitrate solution.
C iron will react with silver nitrate solution.
D silver will react with copper nitrate solution.
- 11 Zinc reacts with copper sulfate solution and silver nitrate solution. This means that zinc:
- A is more reactive than copper and silver.
B is less reactive than copper and silver.
C is less reactive than copper but more reactive than silver.
D is less reactive than silver but more reactive than copper.
- 12 Which of these materials is used to make most car bodies?
- A plastic B aluminium C copper D steel
- 13 Some window frames are made of aluminium. It is a good metal to use because:
- A it conducts electricity.
B it conducts heat.
C it does not melt easily.
D it does not react very quickly with air or water.
- 14 Magnesium would react more slowly with acid if you:
- A added more acid.
B added more water.
C heated the acid.
D used a more concentrated acid.
- 15 Which of these statements is true?
- A Many reactive metals have been known since ancient times.
B Magnesium was discovered before iron.
C Reactive metals can be extracted by heating their compounds with charcoal.
D Most reactive metals were discovered after the invention of the electric battery.

Unreactive metals such as gold and copper have been known since ancient times; reactive metals were only extracted later by electrolysis.

Quick Quiz: Acids & Bases

- 1 When some acid is put onto a piece of metal:
- A there is always a reaction which burns a hole in the metal.
 - B there is never a reaction.
 - C some metals will react with the acid and produce bubbles of gas.
 - D there is always a reaction, which produces a powder.
- 2 Which of the following is the correct way to test for hydrogen gas?
- A Bubble the gas through limewater.
 - B Bubble the gas through universal indicator solution.
 - C Put a glowing splint into a tube of the gas (the splint will burn brightly).
 - D Put a burning splint into a tube of the gas (the gas will explode with a squeaky pop).
- 3 If an acid reacts with a metal, the products are:
- A a salt and water.
 - B a salt and hydrogen gas.
 - C only hydrogen gas.
 - D a salt, water and carbon dioxide.
- 4 Which of the following is **not** needed to make a prediction about the products of a reaction between a metal and an acid?
- A general information about the reactions between metals and acids
 - B information about the properties of the metal
 - C the name of the metal used
 - D the name of the acid used
- 5 When some acid is put onto a piece of rock:
- A it always reacts and gives off a gas.
 - B it reacts if the rock contains a carbonate.
 - C it always reacts explosively and shatters the rock.
 - D it won't react.
- 6 The best test for carbon dioxide uses:
- | | |
|---------------------------------|---------------------|
| A universal indicator solution. | B a burning splint. |
| C litmus paper | D <u>limewater</u> |
- 7 When an acid reacts with a metal carbonate, the products are:
- A the metal and carbon dioxide.
 - B a salt and water.
 - C carbon dioxide, water and a salt.
 - D the metal, a salt and water.

- 4 Which of these is **not** a sign that a reaction has taken place?
 A The substance catches fire.
 B The substance has changed from a solid to a liquid.
 C A gas is given off.
 D There is an explosion.
- 8 A neutral solution is made when:
 A two acids are added together.
 B an acid and an alkali are added together.
 C water is added to an acid.
 D water is added to an alkali.
- 9 When an acid and an alkali react together:
 A a salt and water are both produced.
 B only a salt is produced.
 C a metal is formed.
 D a gas is given off.
- 10 Which of these word equations is correct?
 A copper oxide + hydrochloric acid → copper sulfate + water
 B copper oxide + hydrochloric acid → copper chloride + carbon dioxide + water
 C copper oxide + hydrochloric acid → copper chloride + hydrogen
 D copper oxide + hydrochloric acid → copper chloride + water
- metal oxide + acid → salt + water, e.g. copper oxide + hydrochloric acid → copper chloride + water (copper sulfate is wrong).
- 11 Which of these is **not** a salt?
 A magnesium sulfate
 B iron sulfide
 C tin chloride
 D zinc nitrate
- 12 Which of the following is **not** responsible for making rainwater acidic?
 A lead dioxide
 B carbon dioxide
 C sulfur dioxide
 D nitrogen dioxide
- 13 Which of the following is one of the main causes of acid rain?
 A weathering of rocks
 B photosynthesis in plants
 C power stations burning fossil fuels
 D farmers putting peat on their soil

Burning fossil fuels, which releases sulfur dioxide and nitrogen oxides - both are main causes of acid rain.

Year 9 Types of Reaction Checklist

Reactivity	Green	Amber	Red
I can arrange metals into an order of reactivity, based on their reactions with water and steam.			
I can describe the reactions between some metals and water (eg alkali metals).			
I can describe the reaction between magnesium and steam.			
I can write word and simple balanced symbol equations (from a given formula), for metals reacting with water or steam.			
I can rank metals in order of reactivity based on their reactions with acid and oxygen.			
I can write word equations for metal + oxygen or metal + acid reactions.			
I can write simple balanced equations for metals reacting with oxygen or acid from a given formula.			
I can explain what is meant by a fair test.			
I can define displacement.			
I know that a more reactive metal will displace a less reactive metal from its compounds.			
I can work out the order of reactivity of several metals from results of displacement reactions.			
I can write word equations for displacement reactions.			
I can write simple balanced equations for displacement reactions (when given formulas).			
I can give some uses of common metals (Fe, Cu, Ag, Au) and explain why they are used in this way.			
I can describe the causes, effects and ways to reduce acid rain.			
I know the names and formulas of some common			

acids, bases & salts.			
I can describe the use of universal indicator to identify strong and weak acids and alkalis.			
I can describe how to produce dry crystals of a salt (copper sulphate) by reacting an insoluble metal oxide (copper oxide) with acid (sulphuric acid).			
I can explain the reasons for each step in the method to produce the above salt. For example, heat the acid gently to dissolve more base, filter to remove excess copper oxide.			
I can write word equations and simple balanced equations (when given formula), for metal oxides or alkalis reacting with acids.			
I know that an alkali is a soluble base.			
I know that neutralisation reactions produce heat (are exothermic).			
I can describe how to use the temperature rise to determine the point of neutralisation of an acid and an alkali (by plotting my results on a graph).			

Keywords:

You should be able to use these in a sentence:

Solute, Acid, Base, Alkali, Indicator, Litmus, Universal Indicator, Phenolphthalein, Salts, Weathered, Metal Carbonate, Metal Oxide, Neutralisation, Soluble, Insoluble, Electrolysis, Precipitate, Combustion, Displacement, Reactivity, pH, Thermal Decomposition.

Appendix - answers with no space on the original page

These belong to the printed question on the page shown.

p18: Car bodies are metal because it is strong and malleable, so it can be pressed into shape to protect passengers.

p40: Different metals have different densities and react at very different rates, so it is impossible to use exactly the same amount/surface area of each metal; calcium also reacts so quickly it is hard to time fairly.

p66: chlorine

p66: hydrogen
